UNNUMBERED A ZONES

History of Unnumbered A Zones

In the beginning we had to guess....

We had a lack of resources

Even now sometimes we have to guess..... But WHY???

Because detailed floodplain studies are expensive, really expensive.

Many rural areas were estimated using approximate techniques.

The bad news

Even without an established Base Flood Elevation it is still necessary to ensure that development is reasonably safe from flood damage.

And what is reasonable safe from flood damage exactly???

HFIF is the adoption and enforcement of floodplain management regulations that meet the minimum standards of the MFIF regulations in Title 44 of the Code of Federal Regulations (CFR) Section 60.1. These minimum standards wary depending on the type of flood risk data provided to the community by FEMA. The intent of floodplain management regulations is to minimize the potential foor flood hasned to new commuture that could increase potential flood danages to existing structures. To protect structures in riverise and larmatrize areas, the MFIF regulations regular that the lowest floor (including hasness) to additional increase be elevated to or above the MFE. Mer or substantially lagraved non-residential structures in riverine areas must either be sizested or floodproofed (make watertight) to or above the HFE.

Floodplain Management

Requirements for Obtaining BFE Data

Guide For Approximate Some & Areas

In areas designated as approximate form A, where AFRs have not been provided by FRMA, communities must apply the provisions of Fersymph 60.3(b) of the HTTP regulations. Subparagraph 67.3(b)(4) requires that communities:

Obtain, review and reasonably utilize any base flood elevation and floodway data evailable from a Pederal, Ptate, or other source... 144 CF8 60-2 (b)(4) 1

Section 1V describes the sources from which EFE data may be obtained. These data are to be used as criteria for requiring that new construction, substantial improvements, and other development within all approximate Zone A areas meet the applicable requirements in Petergraphs 60.3(ni and (d) of the NFTP regulations, including the requirement that structures thave their lowest floors elevated to or above the EFE for floodproofed to or above the BFE for non-remidential structures). These data should be used as long as they reasonably reflect flooding combining separate during the base (100-year) flood, are not known to be scientifically or technically incorrect, and represent the best data scallable. Communities about consider formally adopting these data by

Great so how do I establish a base flood elevation??

There are multiple options, you just have to figure out what works for the particular case.

- FEMA Publication 265
 - Simplified Methods
 - Contour Interpolation
 - Data Extrapolation
 - Detailed Method
 - Topography
 - Hydrology
 - Hydraulics
- Letter of Map Amendment

FEDERAL EMERGENCY MANAGEMENT AGENCY	FEMA 265/R/LY 1995
MANAGING FLOODPLAIN DEV	ELOPMENT
IN	
APPROXIMATE ZONE A	A AREAS
A GUIDE FOR OBTAINING AND I	
BASE (100-YEAR) FLOOD ELE	VATIONS
APRE. 1995	

Contour Interpolation

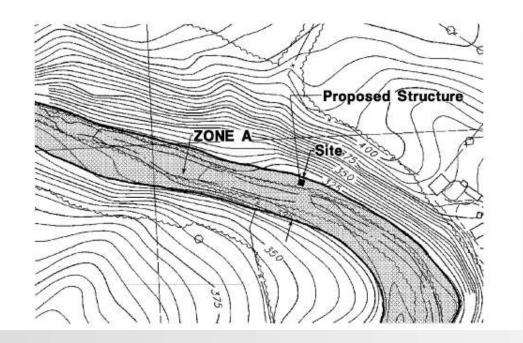

- Obtain a topographic map
- Scale the FIRM or topographic map so the two are at the same scale
- Superimpose the approximate A zone floodplain boundary from the FIRM onto the topographic map
- Determine if this method is within the acceptable accuracy limits.
- If the method is acceptable then determine the Base Flood Elevation.

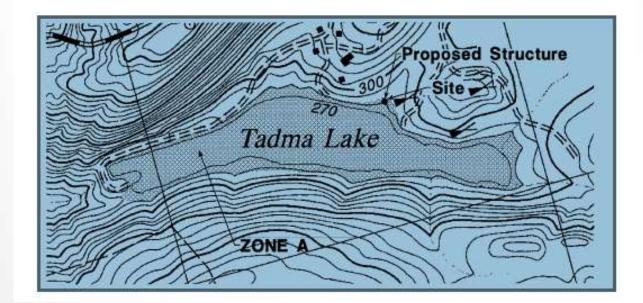

What is an acceptable accuracy limit???

According to FEMA – 265:

1/2 of one contour interval

Data Extrapolation

If a site is within 500 feet upstream of a stream reach for which a 1% flood profile has been computed by detailed methods, and the floodplain channel bottom slope characteristics are relatively similar to the downstream reaches, data extrapolation may be used to determine the BFE.

- Must be free of backwater effects from downstream hydraulic structures (Bridges, culverts, etc.)
- If the 1% flood profile changes just prior to the limit of detailed study, this method should not be used.
- Determine the location of the site on the flood profile for the detailed study steam study.
- Extrapolate the last segment of the 100-year flood profile that has a constant water-surface slope to the location of the site. The BFE at the site
 CAN be obtained directly from the profile.

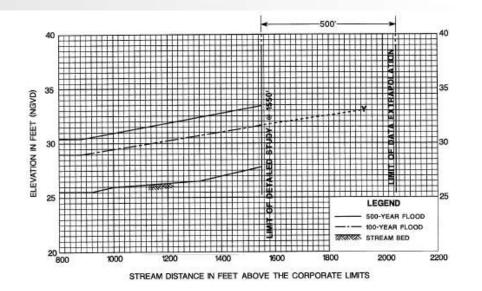

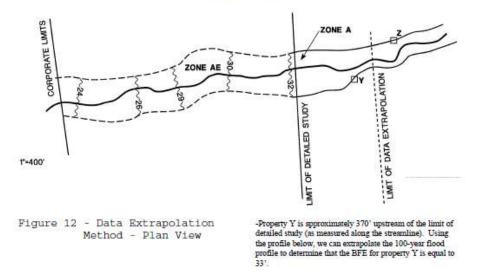

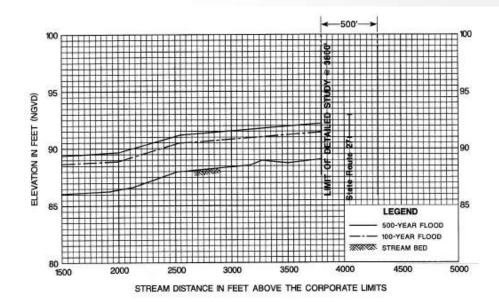

Figure 11 - Data Extrapolation Method - Profile

17 0

 -Property Z is approximately 700' upstream of the limit of detailed study (as measured along the streamline), and is therefore beyond the limit of data extrapolation.

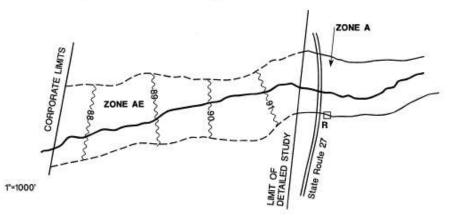

Figure 14 - Data Extrapolation Method - Plan View

-State Route 27 may have an effect on the 100-year water-surface elevations. Therefore, data extrapolation should not be used to obtain a BFE for property R.

Detailed Method

Topography Hydrology Hydraulics

Topography

To create cross sections you will need good elevation data. Watch out for datum.

10 foot Contours – BAD 1 foot Contours – Good

How many cross sections?

For one lot technically only one cross section is required, for large parcels of multi-lot subdivisions at least one cross section is required at each end of the parcel or subdivision.

Topography

Proper location of cross sections is imperative

Cross sections:

- Must be perpendicular to the flood path of the 1% flood
- Should be located where changes in channel characteristics, such as slope, shape, and roughness occur
- Should be located at points along a stream where changes in flood discharge occur, such as upstream of tributaries
- A minimum of two cross sections are required to compute a BFE at or near a structure, such as a bridge or culvert.

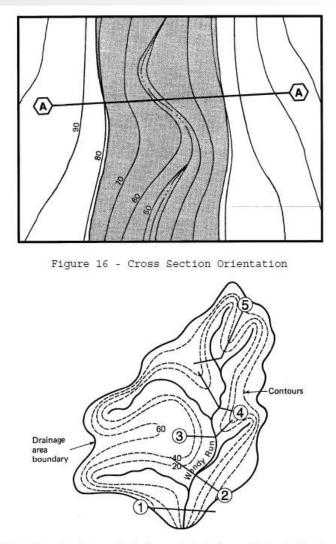

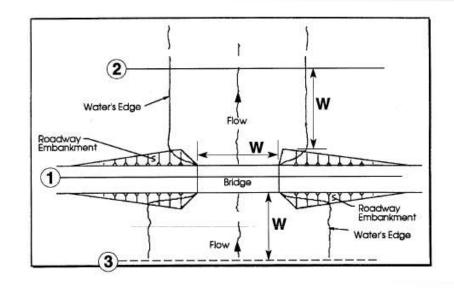

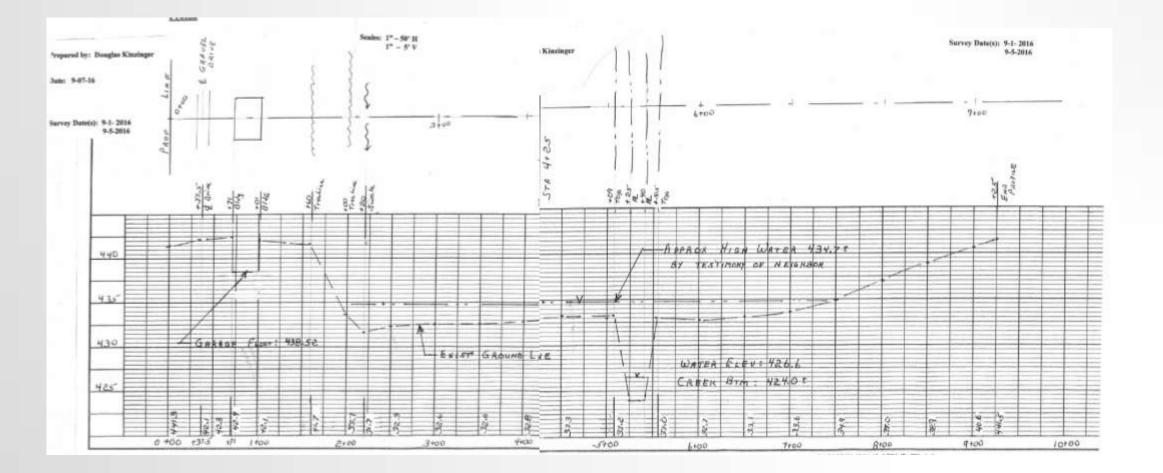

Figure 17 - Locate Cross Sections at Points of Flood Discharge Changes

Hydrology

There are a number of methodologies that may be used to develop flood discharges. Each method has its own ease of use and own level of accuracy.

- Discharge-Drainage Area Relationships
- Regression Equations (Q=K * $A^X * B^Y * C^Z$)
- NRCS TR-55 "Urban Hydrology for Small Watersheds"
- Rational Formula (Q=C * I * A)
- Other Hydrograph Methods (Stream Stats

Rational Formula (Q=C * I * A)

- = Discharge (cubic feet per second Q С
 - = Runoff coefficient
 - = Rainfall intensity (inches per hour)
- = Drainage area (acres) Α
- Limitations This method must not be used where the runoff is regulated by the use of dams, detention ponds, canals, and other flow diversions. Also this method is not recommended for drainage areas greater than 200 acres, but can be used with caution for drainage areas up to 640 acres (one square mile).

Hydraulics

There are various methods to determine BFE's

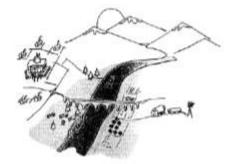

- Hand Calculations
- HEC-RAS
- WSP2

What has to be computed?

- Normal Depth
- Critical Depth
- Step-Backwater Analysis
- Hydraulic Structures
 - Weir flow
 - Flow through structure (culverts and bridges)

HEC-RAS River Analysis System

A first time buyer approaches the Building Department.

"Can you give us some advice and help us place the foundation."

I can certainly look at it, however, you may need an engineer.

When reviewing requests for building permits or site plans remember:

Simply stated, whenever one is developing in an urban area, if the

Watershed is greater than one square mile (10 square miles for rural) then

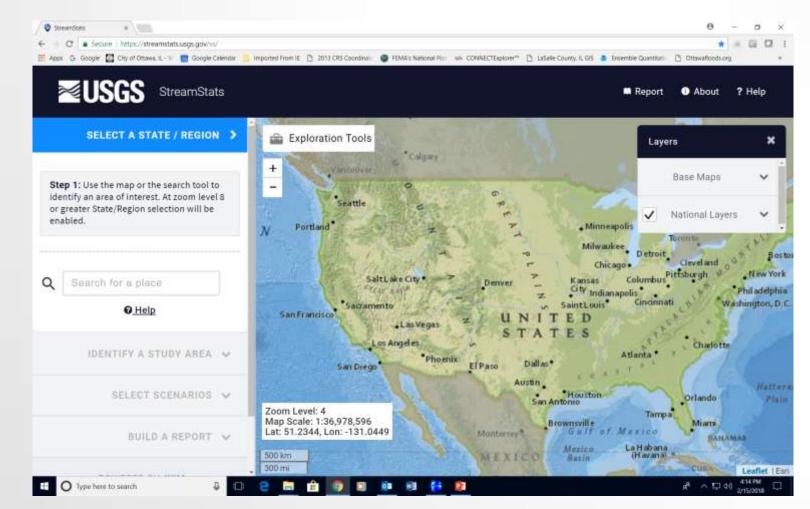

a Base Flood Elevation must be determined.

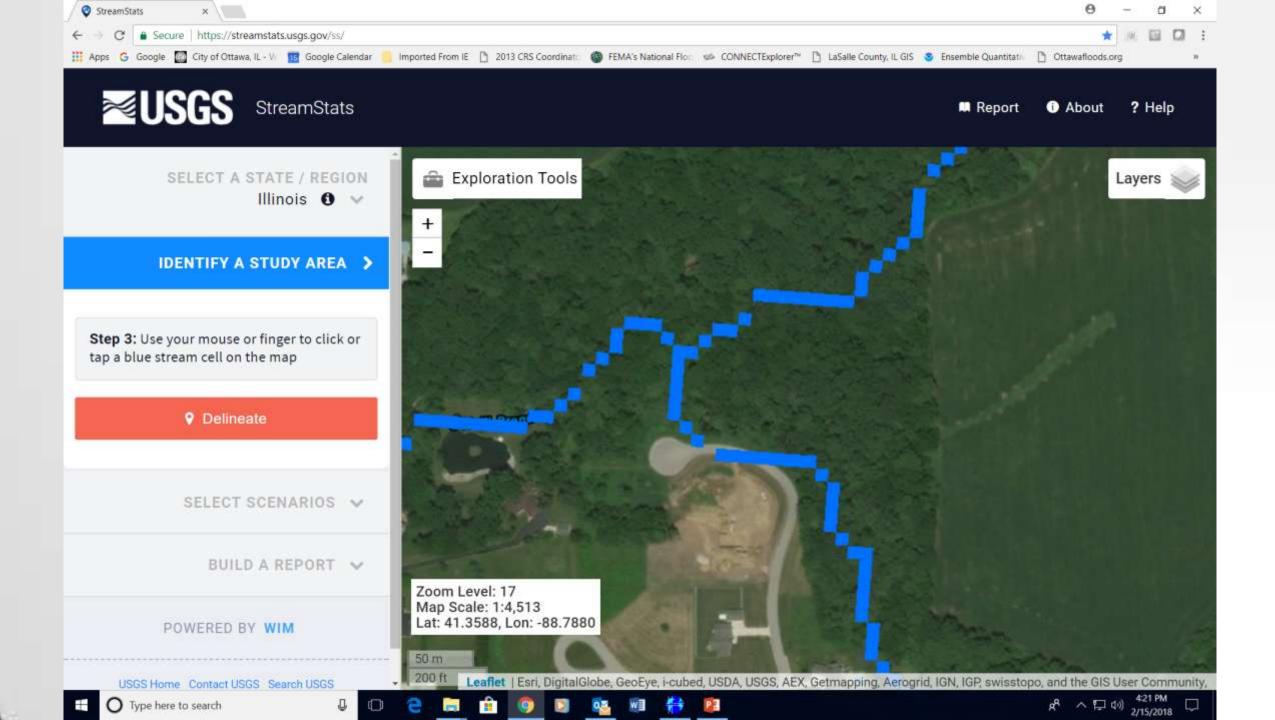

HOW DOES ONE DETERMINE THE WATERSHED?

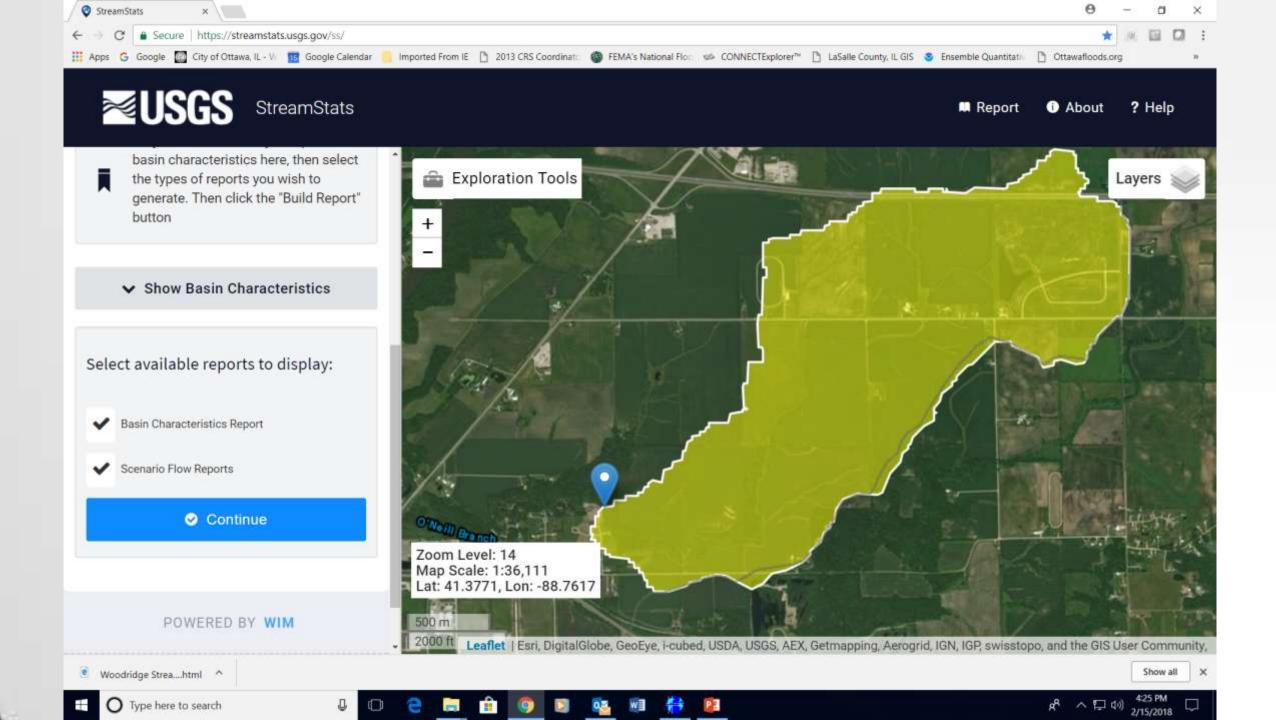

One could hire and engineering firm to do a H & H study. Lots of \$\$.

Or to get a good idea, turn to US Geological Survey

642 Cubic Feet per Second 7.48 Gallons per Cubic Foot 642 x 7.48 = 4802 Gallons per Second Or 288,120 Gallons per minute!

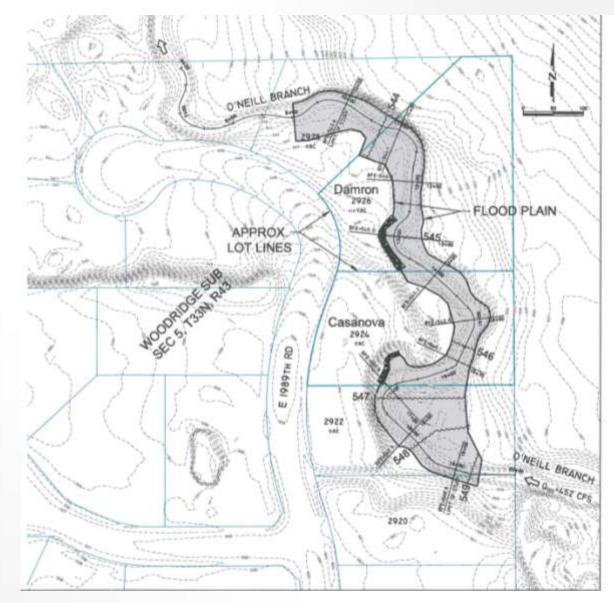

TIME FOR A HYDRAULIC ANALYSIS TO DETERMINE THE BFE

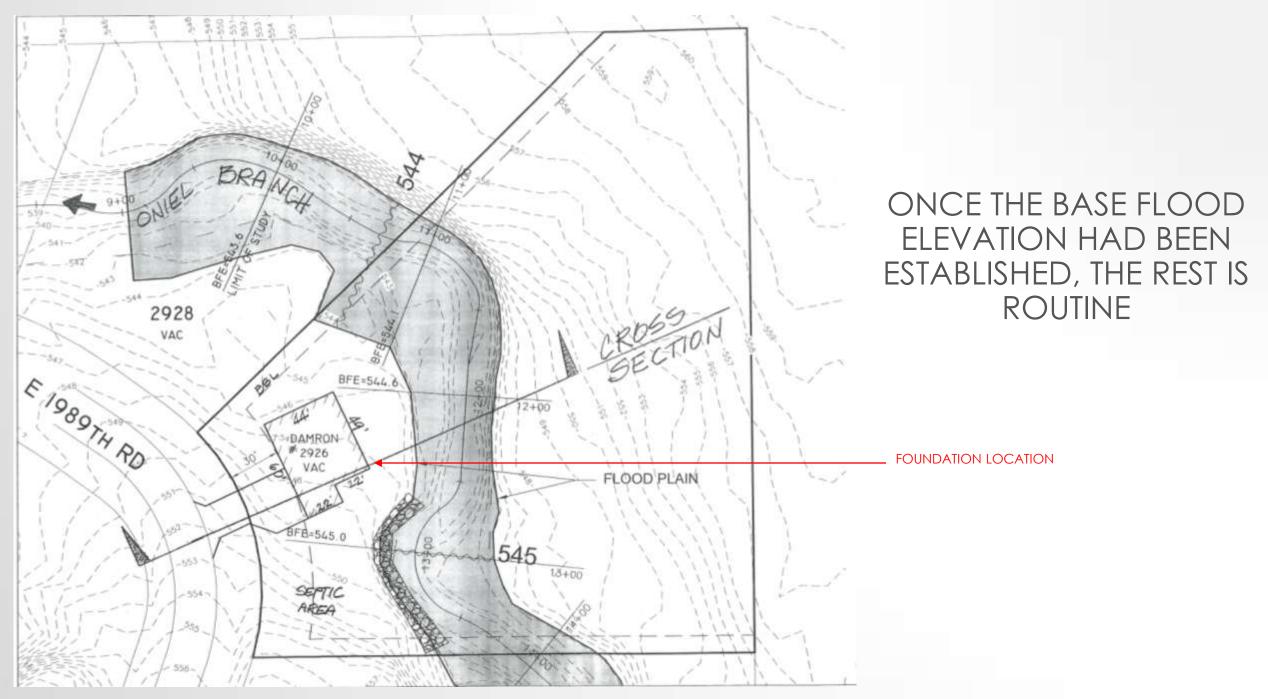

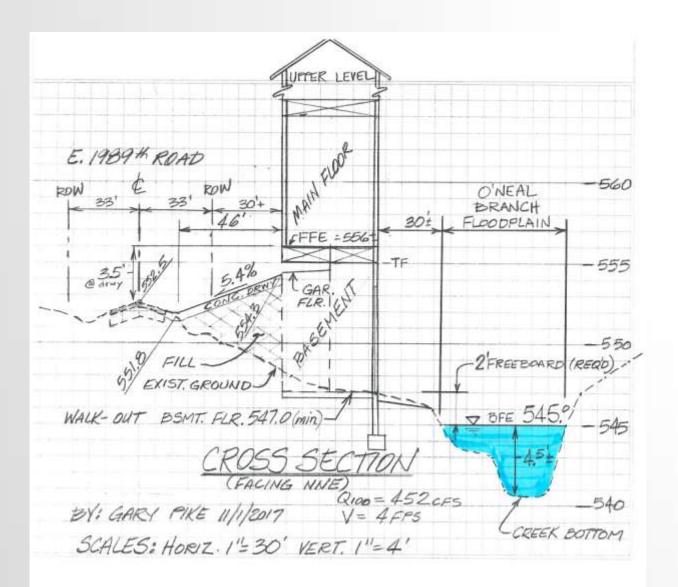

"One of the keys to affordability of this flood study project was the availability of the City's topographic mapping with 1' contour interval.

In the absence of such mapping we must perform conventional stream cross section surveys, which can impact the affordability of the flood study." Consulting Engineer

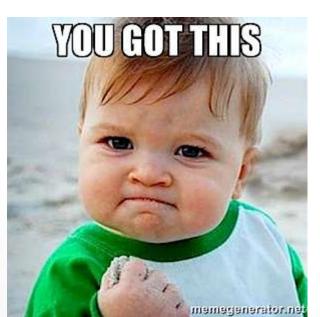

- 1. Provides certainty that the codes are met, i.e., freeboard, compensatory storage, septic placement, etc.
- 2. An elevation certificate after construction will ensure the building is outside the SFHA.

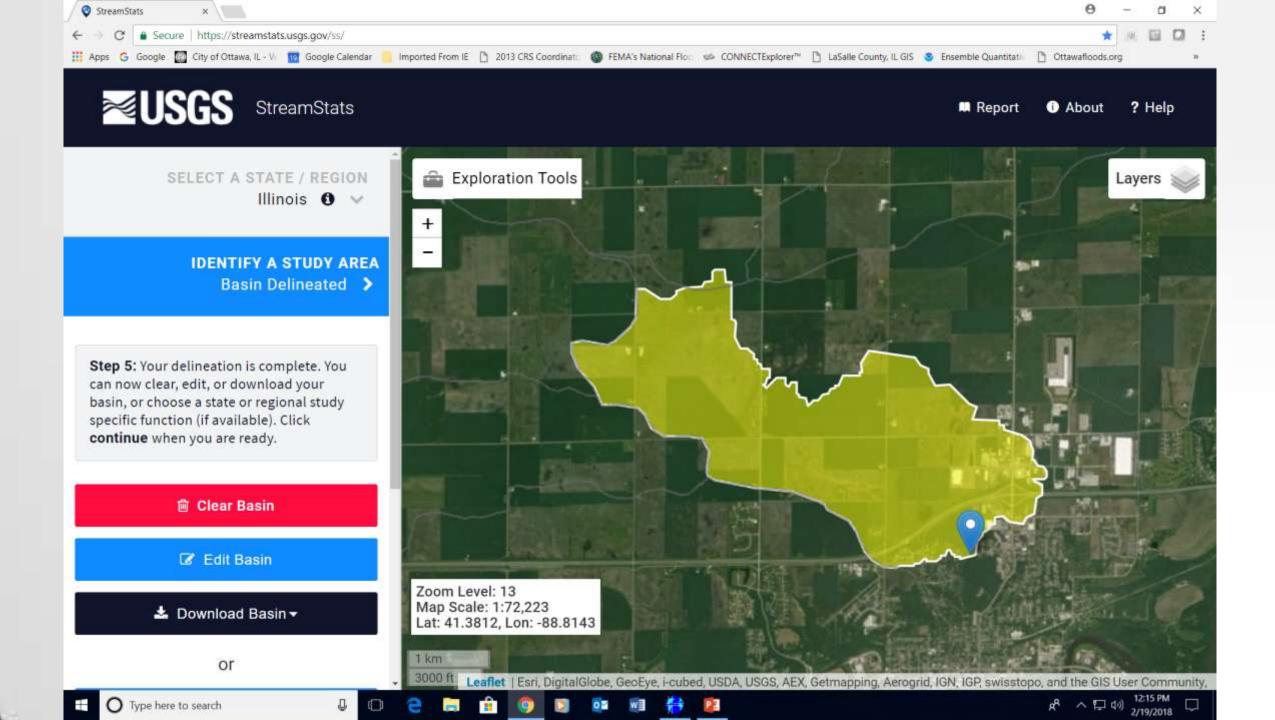

Case # 2

DEER CREEK SUBDIVISION AT THE GOOSE CREEK

1st time home buyer asked for help locating the foundation.

Another area not mapped

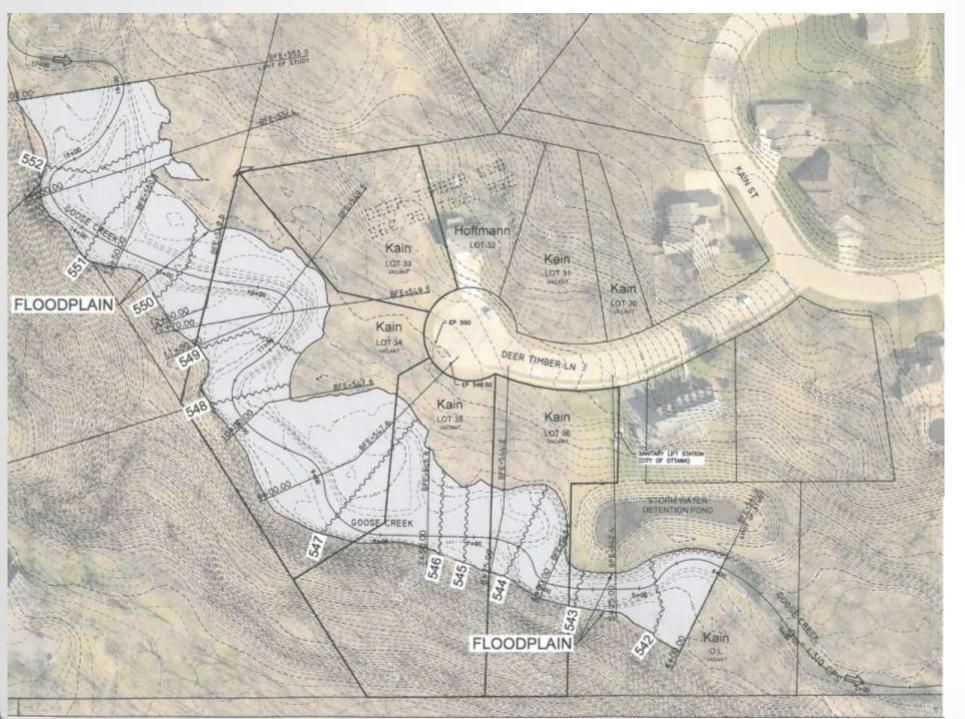

USGS REPORT SHOWS PEAK FLOW FOR THE 1% EVENT IS 1310 CFS

THAT IS ABOUT 587,928 GALLONS PER MINUTE

ONCE AGAIN, ONE FOOT CONTOUR INFORMATION KEEPS THE STUDY AFFORDABLE AND WAS NOT A DEAL BREAKER FOR THE BUYER

At first the developer was upset and reluctant to commit to have the study done.

The buyer was insistent and refused to move further without this information.

The City refused to issue a building permit without this information

The submitted site plan had to be changed as the foundation (walkout) would have been in the floodplain.

Better information prevents flood damage.
